## Design of Steel Structures

---

### 1. Introduction

C. C. Fu, Ph.D., P.E.  
Civil and Environmental Engineering Department  
University of Maryland

## Introduction

---

Following subjects are covered:

- Structural Design
- Types of Loads
- Specifications for design of steel structures
- Structural steel
- Grades of steel
- Steel shapes
- Properties of structural steel
- Design philosophy

Reading:

- Chapters 1 and 2 of Segui
- AISC Steel Construction Manual, 13th Ed.

2

## Structural Design

---

- **Definition:** Determination of overall proportions and dimensions of the supporting framework and the selection of individual members.
- **Responsibility:** The structural engineer, within the constraints imposed by the architect (number of stories, floor plan,..) is responsible for structural design.

3

## Important Factors in Design

---

- **Safety** (the structure doesn't fall down)
- **Serviceability** (how well the structure performs in term of appearance and deflection)
- **Economy** (an efficient use of materials and labor)

4

## Design Specifications

- Provide **guidance** for the design of structural members and their connections.
- They have **no legal standing on their own**, but they can easily be adopted, by reference, as part of a building code.

5

## Steel Specifications

### Main:

- American Institute of Steel Construction (AISC) - Design of steel buildings and connections ([www.aisc.org](http://www.aisc.org))
- American Association of State Highway and Transportation Officials (AASHTO) - Design of steel/reinforced concrete/timber bridges ([www.aashto.org](http://www.aashto.org))

### Others:

- American Iron and Steel Institute (AISI) - Cold-formed steel structures ([www.steel.org](http://www.steel.org))
- American Railway Engineering and Maintenance of Way Association - Steel railway bridges ([www.arena.org](http://www.arena.org))

(see AISC Manual pp 2-4 thru 2-7)

6

## Building Code

- A **legal document** containing requirements related to such things as structural safety, fire safety, plumbing, and ventilation.
- It has the **force of law** and is administered by a city, a county, or other governmental agencies.
- It does not provide design procedures, but it **specifies the design requirements**.

7

## National Model Codes

- Most of the municipalities adopt a model code and modify it to suit their particular needs.
- The **BOCA** National Building Code
- The Uniform/International Building Code (**UBC/IBC**)
- The Standard Building Code
  - The ASCE7-02, Minimum Design Loads for Building and Other Structures, is another nationally accepted document.

8

## Types of Load

- **Dead Loads** (permanent; including self-weight, floor covering, suspended ceiling, partitions,..)
- **Live Loads** (not permanent; the location is not fixed; including furniture, equipment, and occupants of buildings)
- **Wind Load** (exerts a pressure or suction on the exterior of a building)

9

## Types of Load (Cont.)

- **Earthquake Loads** (the effects of ground motion are simulated by a system of horizontal forces)
- **Snow Load** (varies with geographical location and drift)
- **Other Loads** (hydrostatic pressure, soil pressure)

10

## Types of Load (Cont.)

- If the load is applied suddenly, the effects of **IMPACT** must be accounted for.
- If the load is applied and removed many times over the life of the structure, **FATIGUE** stress must be accounted for

11

## History of Structural Steel

### Iron

- Chief component of steel
- Wrought iron first used for tools around 4000 BC
- Produced by heating ore in a charcoal fire
- Cast and wrought iron used in the late 18C and early 19C
- in bridges

12

## History of Structural Steel (cont.)

### Structural Steel

- Steel is an alloy of primarily iron, carbon (1 to 2%) and small amount of other components (manganese, nickel, ...)
- Fewer impurities and less carbon than cast iron
- Carbon contributes to strength but reduces ductility.
- Began to replace iron in construction in the mid 1800s
- First steel railroad bridge in 1874
- First steel framed building in 1884

13

## Grade of Steel

Numerous grades of steel are available in the marketplace. The choice is dependent on

- Application
- Yield strength
- Composition

See the summaries on the AISC Manual Tables 2-1 thru 2-3 (Page 2-37 thru 2-39)

14

## Steel Shapes

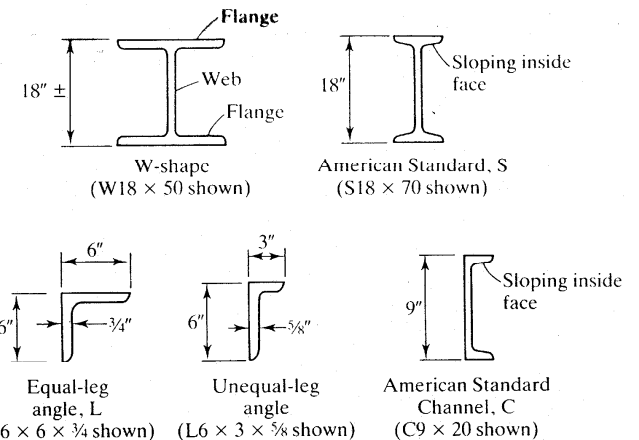

Hot-rolled shapes are produced from molten steel in a furnace that is poured into a continuous casting where the steel solidifies but does not cool completely. The partially cooled steel is then passed through rollers to achieve the desired shape.

15

## Standard Cross-Sectional Shapes

W4 - W44  
 M3 - M12.5  
 S3 - S24  
 H8 - H14  
 C3 - C15  
 MC3 - MC18  
 L2½xL1½ - L8x8  
 WT2 - WT22  
 MT2 - MT6.25  
 ST1.5 - ST12

## Standard Cross-Sectional Shapes

HSS2x1 – 20x12

HSS1.660 – 20.000

Pipe ½ Std. – 12 Std.  
(x-Strong, xx-Strong)

17

## Standard Cross-Sectional Shapes

2L (LLBB or SLBB): 2L2x2 – 2L8x8

2C: 2C3 – 2C15

2MC: 2MC3 – 2MC18

18

## Camber and Sweep

19

## Steel Properties

- The important characteristics of steel for design purposes are:
  - yield stress ( $F_y$ )
  - ultimate stress ( $F_u$ )
  - modulus of elasticity ( $E$ )
  - percent elongation ( $\epsilon$ )
  - coefficient of thermal expansion ( $\alpha$ )

20

# The Tension Test

4 Ranges of responses:

- Elastic
- Plastic (yield plateau)
- Strain hardening
- Necking and failure (strain softening)

# Effect of Temperature on the Properties of Steel

- Elevated temperatures generally **degrade the properties of structural steel**. Threshold temperatures vary as a function of mechanical property under consideration.
- Temperatures below room temperature do not have an adverse effect on  $\sigma_y$  but can have a significant effect on **ductility**.
- Behavior will transform from ductile to brittle at a threshold temperature range known as the Ductile-to-Brittle Transition Temperature (**DBTT**) range.

(See AISC Manual pp 2-30 thru 2-33)

# Effect of Temperature on the Properties of Steel (cont.)

- For sample information on the effect of temperature on **yield stress**, **tensile strength**, and **Young's modulus**

# Material Toughness

- **Charpy V-notch test** was introduced
- Result of the test is a value for notch toughness (**CVN**) given by xx ft-lb at yy F. This is a characterization of the energy absorbed by the notched specimen

(See AISC Manual pp 2-33 thru 2-35)

## Material Toughness (cont.)

### Charpy V-notch test

25

## Design Philosophies

- Allowable Stress Design Method (ASD)
- Load and Resistance Factor Design (LRFD)

26

## ASD

- A member is selected such that the max stress due to working loads does not exceed an allowable stress.
- It is also called elastic design or working stress design.
  - F.S. =  $R_n/Q$  where  $R_n$  is the nominal strength and  $Q$  is the nominal service load
  - Allowable stress = Yield stress / Factor of Safety  $\Omega$
  - Actual stress  $\leq$  Allowable stress

27

## LRFD

- A member is selected such that its factored strength is more than the factored loads.
  - $\Sigma(\text{L factors} \times \text{Loads}) \leq \text{R factor} \times \text{Resistance}$   
 $\Sigma(\gamma_i \times Q_i) \leq \phi \times R_n$
- Each load effect (DL, LL, ..) has a different load factor which its value depends on the combination of loads under consideration.

28

## Basis of LRFD

- The **load and resistance factors** are based on extensive analytical studies and assessment of in-service conditions.
- **Load factors** account for randomness in load effects
- **Resistance factors** account for randomness in material properties and uncertainties in analysis and design theory, and fabrication and construction practices.
- Consideration is given to **Mean, Variance, Standard Deviation, and Coefficient of Variation**

29

## Basis of LRFD (cont.)

Fig. 3.4 Probability density functions for load and resistance.

30

## Basis of LRFD (cont.)

Fig. 3.5 Definition of safety index for lognormal  $R$  and  $Q$ .

31

## Basis of LRFD (cont.)

Load Combinations	Objective Reliability Index $\beta$
Dead load + Live load (or Snow load)	<b>3.0</b> for members <b>4.5</b> for connections
Dead load + Live load + Wind load	<b>2.5</b> for members
Dead load + Live load + Earthquake load	<b>1.75</b> for members

where Reliability Index  $\beta$

$$\beta = \frac{\ln(R_m / Q_m)}{\sqrt{V_R^2 + V_Q^2}}$$

32

## Load Factors

- The values are based on extensive statistical studies
    - DL only 1.4D
    - DL+LL+SL (LL domin.)  $1.2D+1.6L+0.5S$
    - DL+LL+SL (SL domin.)  $1.2D+0.5L+1.6S$
    - In each combination, one of the effects is considered to be at its "lifetime" max value and the others at their "arbitrary point in time" values.
- (see AISC Manual pp 2-8 thru 2-10)

33

## Resistance Factor

- The resistance factors range in value from 0.75 to 1.0 depending on the type of resistance (tension, bending, compression, ..)
- These factors account for uncertainties in material properties, design theory, and fabrication and construction practices.

34

## History

- ASD has been the primary method used for steel design since the first AISC specifications was issued in 1923.
- In 1986, AISC issued the first specification for LRFD.
- The trend today is toward LRFD method, but ASD is still in use.

35

## Advantages of LRFD

- It provides a **more uniform reliability** in all structures subjected to many types of loading conditions. It does not treat DL and LL as equivalent, thereby leading to a more rational approach.
- It provides **better economy** as the DL make up a greater percentage on a given structure.
  - Because DLs are less variable by nature than live loads, a lower load factor is used.
  - This may lead to a reduction in member size and therefore better economy.
- **AISC Video** ([National Environmental Report.mht](#))
