# Cryptography

Lecture 11

#### **Announcements**

- HW4 due today
- Midterm Upcoming on Wednesday 3/13
  - Review sheet posted on course webpage
  - On Canvas
    - Cheat Sheet
    - Extra practice folder with last year's HW5 and solutions as well as an additional class exercise

### Agenda

- Last time:
  - MACs (K/L 4.1, 4.2, 4.3)
- This time:
  - Domain Extension for MACs (K/L 4.4) and Class Exercise solutions
  - CCA security (K/L 3.7)
  - Authenticated Encryption (K/L 4.5)

### Message Authentication Codes

Definition: A message authentication code (MAC) consists of three probabilistic polynomial-time algorithms (Gen, Mac, Vrfy) such that:

- 1. The key-generation algorithm Gen takes as input the security parameter  $1^n$  and outputs a key k with  $|k| \ge n$ .
- 2. The tag-generation algorithm Mac takes as input a key k and a message  $m \in \{0,1\}^*$ , and outputs a tag t.  $t \leftarrow Mac_k(m)$ .
- 3. The deterministic verification algorithm Vrfy takes as input a key k, a message m, and a tag t. It outputs a bit b with b=1 meaning valid and b=0 meaning invalid.  $b\coloneqq Vrfy_k(m,t)$ .

It is required that for every n, every key k output by  $Gen(1^n)$ , and every  $m \in \{0,1\}^*$ , it holds that  $Vrfy_k(m, Mac_k(m)) = 1$ .

## Security of MACs

The message authentication experiment  $MACforge_{A,\Pi}(n)$ :

- 1. A key k is generated by running  $Gen(1^n)$ .
- 2. The adversary A is given input  $1^n$  and oracle access to  $Mac_k(\cdot)$ . The adversary eventually outputs (m, t). Let Q denote the set of all queries that A asked its oracle.
- 3. A succeeds if and only if (1)  $Vrfy_k(m,t) = 1$  and (2)  $m \notin Q$ . In that case, the output of the experiment is defined to be 1.

# Security of MACs

Definition: A message authentication code  $\Pi = (Gen, Mac, Vrfy)$  is existentially unforgeable under an adaptive chosen message attack if for all probabilistic polynomial-time adversaries A, there is a negligible function neg such that:

$$\Pr[MACforge_{A,\Pi}(n) = 1] \leq neg(n)$$
.

#### Strong MACs

The strong message authentication experiment  $MACsforge_{A,\Pi}(n)$ :

- 1. A key k is generated by running  $Gen(1^n)$ .
- 2. The adversary A is given input  $1^n$  and oracle access to  $Mac_k(\cdot)$ . The adversary eventually outputs (m, t). Let Q denote the set of all pairs (m, t) that A asked its oracle.
- 3. A succeeds if and only if (1)  $Vrfy_k(m,t) = 1$  and (2)  $(m,t) \notin Q$ . In that case, the output of the experiment is defined to be 1.

#### Strong MACs

Definition: A message authentication code  $\Pi = (Gen, Mac, Vrfy)$  is a strong MAC if for all probabilistic polynomial-time adversaries A, there is a negligible function neg such that:  $\Pr[MACsforge_{A,\Pi}(n) = 1] \leq neg(n)$ .

## Domain Extension for MACs

#### CBC-MAC

Let F be a pseudorandom function, and fix a length function  $\ell$ . The basic CBC-MAC construction is as follows:

- Mac: on input a key  $k \in \{0,1\}^n$  and a message m of length  $\ell(n) \cdot n$ , do the following:
  - 1. Parse m as  $m=m_1,\ldots,m_\ell$  where each  $m_i$  is of length n.
  - 2. Set  $t_0 \coloneqq 0^n$ . Then, for i = 1 to  $\ell$ : Set  $t_i \coloneqq F_k(t_{i-1} \oplus m_i)$ .

Output  $t_{\ell}$  as the tag.

• Vrfy: on input a key  $k \in \{0,1\}^n$ , a message m, and a tag t, do: If m is not of length  $\ell(n) \cdot n$  then output 0. Otherwise, output 1 if and only if  $t = Mac_k(m)$ .

#### **CBC-MAC**

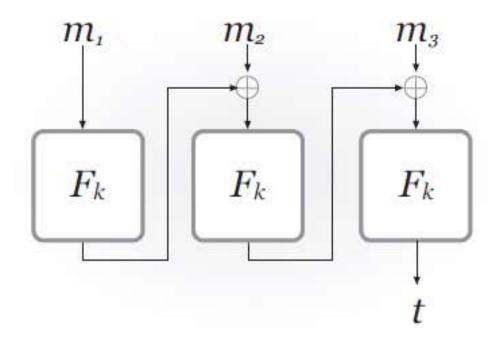

FIGURE 4.1: Basic CBC-MAC (for fixed-length messages).

# **Chosen Ciphertext Security**

#### **CCA Security**

The CCA Indistinguishability Experiment  $PrivK^{cca}_{A,\Pi}(n)$ :

- 1. A key k is generated by running  $Gen(1^n)$ .
- 2. The adversary A is given input  $1^n$  and oracle access to  $Enc_k(\cdot)$  and  $Dec_k(\cdot)$ , and outputs a pair of messages  $m_0, m_1$  of the same length.
- 3. A random bit  $b \leftarrow \{0,1\}$  is chosen, and then a challenge ciphertext  $c \leftarrow Enc_k(m_h)$  is computed and given to A.
- 4. The adversary A continues to have oracle access to  $Enc_k(\cdot)$  and  $Dec_k(\cdot)$ , but is not allowed to query the latter on the challenge ciphertext itself. Eventually, A outputs a bit b'.
- 5. The output of the experiment is defined to be 1 if b' = b, and 0 otherwise.

### **CCA Security**

A private-key encryption scheme  $\Pi = (Gen, Enc, Dec)$  has indistinguishable encryptions under a chosen-ciphertext attack if for all ppt adversaries A there exists a negligible function negl such that

$$\Pr\left[PrivK^{cca}_{A,\Pi}(n) = 1\right] \le \frac{1}{2} + negl(n),$$

where the probability is taken over the random coins used by A, as well as the random coins used in the experiment.

# **Authenticated Encryption**

The unforgeable encryption experiment  $EncForge_{A,\Pi}(n)$ :

- 1. Run  $Gen(1^n)$  to obtain key k.
- 2. The adversary A is given input  $1^n$  and access to an encryption oracle  $Enc_k(\cdot)$ . The adversary outputs a ciphertext c.
- 3. Let  $m \coloneqq Dec_k(c)$ , and let Q denote the set of all queries that A asked its encryption oracle. The output of the experiment is 1 if and only if  $(1) \ m \neq \bot$  and  $(2) \ m \notin Q$ .

# **Authenticated Encryption**

Definition: A private-key encryption scheme  $\Pi$  is unforgeable if for all ppt adversaries A, there is a negligible funcion neg such that:

$$\Pr[EncForge_{A,\Pi}(n) = 1] \le neg(n)$$
.

Definition: A private-key encryption scheme is an authenticated encryption scheme if it is CCAsecure and unforgeable.
