

Cryptography ENEE/CMSC/MATH 456: Homework 5

Due by beginning of class on 3/13/2023.

1. Recall our construction of CPA-secure encryption from PRF (Construction 3.28 in the textbook). Show that while providing secrecy, this encryption scheme *does not* provide message integrity. Specifically, show that an attacker who sees a ciphertext $c := \langle r, s \rangle$, but does not know the secret key k or the message m that is encrypted, can still create a ciphertext c' that encrypts $m \oplus 1^n$.
2. Say $\Pi = (\text{Gen}, \text{Mac}, \text{Vrfy})$ is a secure MAC, and for $k \in \{0, 1\}^n$, the tag-generation algorithm Mac_k always outputs tags of length $t(n)$. Prove that t must be super-logarithmic or, equivalently, that if $t(n) = O(\log n)$ then Π cannot be a secure MAC.
Hint: Consider the probability of randomly guessing a valid tag.
3. Consider the following MAC for messages of length $\ell(n) = 2n - 2$ using a pseudorandom function F : On input a message $m_0 || m_1$ (with $|m_0| = |m_1| = n - 1$) and key $k \in \{0, 1\}^n$, algorithm Mac outputs $t = F_k(0 || m_0) || F_k(1 || m_1)$. Algorithm Vrfy is defined in the natural way. Is $(\text{Gen}, \text{Mac}, \text{Vrfy})$ secure? Prove your answer.
4. Let F be a pseudorandom function. Show that each of the following MACs is insecure, even if used to authenticated fixed-length messages. (In each case Gen outputs a uniform $k \in \{0, 1\}^n$. Let $\langle i \rangle$ denote an $n/2$ -bit encoding of the integer i .)
 - (a) To authenticate a message $m = m_1, \dots, m_\ell$, where $m_i \in \{0, 1\}^n$, compute $t := F_k(m_1) \oplus \dots \oplus F_k(m_\ell)$.
 - (b) To authenticate a message $m = m_1, \dots, m_\ell$, where $m_i \in \{0, 1\}^{n/2}$, compute $t := F_k(\langle 1 \rangle || m_1) \oplus \dots \oplus F_k(\langle \ell \rangle || m_\ell)$.
