## Lecture 22

# Announcements

- HW5 due on 4/24 at 11:59pm
- HW6 posted, due on 5/8 at 11:59pm
- No lecture (or quizzes) on 4/24 and 4/29
  - Please watch videos linked in the Canvas announcement

# Agenda

- Last time:
  - Diffie-Hellman Key Exchange
  - Public Key Encryption
  - ElGamal (11.5)
- This time:
  - Digital Signatures Definitions (13.2)
  - DL-Based Signatures (13.5)

# Digital Signatures = CERT

Sender

Receiver

$$\text{Gen}(1^n) \rightarrow (\underline{pk}, sk)$$

$$m \leftarrow \text{Sign}_{sk}(m) \xrightarrow{(m, \sigma)} \text{Vrfy}_{pk}(m, \sigma) = 0/1$$

0 = bad  
1 = good

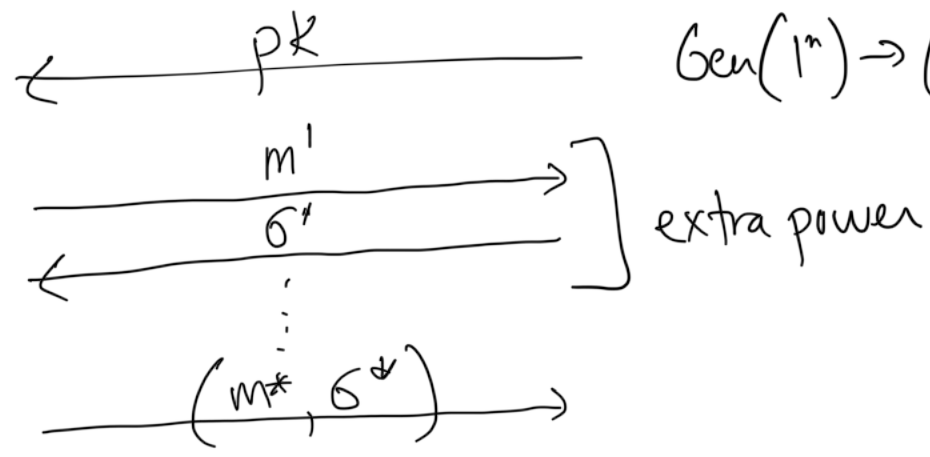

Security Game:

CMA  
chosen message attack

Chall

$$\text{Gen}(1^n) \rightarrow (pk, ck)$$

$$m^* \notin Q, \text{ and } \text{Vrfy}_{pk}(m^*, \sigma^*) = 1.$$

# Digital Signatures Definition

A digital signature scheme consists of three ppt algorithms  $(Gen, Sign, Vrfy)$  such that:

1. The key-generation algorithm  $Gen$  takes as input a security parameter  $1^n$  and outputs a pair of keys  $(pk, sk)$ . We assume that  $pk, sk$  each have length at least  $n$ , and that  $n$  can be determined from  $pk$  or  $sk$ .
2. The signing algorithm  $Sign$  takes as input a private key  $sk$  and a message  $m$  from some message space (that may depend on  $pk$ ). It outputs a signature  $\sigma$ , and we write this as  $\sigma \leftarrow Sign_{sk}(m)$ .
3. The deterministic verification algorithm  $Vrfy$  takes as input a public key  $pk$ , a message  $m$ , and a signature  $\sigma$ . It outputs a bit  $b$ , with  $b = 1$  meaning valid and  $b = 0$  meaning invalid. We write this as  $b := Vrfy_{pk}(m, \sigma)$ .

**Correctness:** It is required that except with negligible probability over  $(pk, sk)$  output by  $Gen(1^n)$ , it holds that  $Vrfy_{pk}(m, Sign_{sk}(m)) = 1$  for every message  $m$ .

# Digital Signatures Definition: Security

Experiment  $SigForge_{A,\Pi}(n)$ :

1.  $Gen(1^n)$  is run to obtain keys  $(pk, sk)$ .
2. Adversary  $A$  is given  $pk$  and access to an oracle  $Sign_{sk}(\cdot)$ . The adversary then outputs  $(m, \sigma)$ . Let  $Q$  denote the set of all queries that  $A$  asked to its oracle.
3.  $A$  succeeds if and only if
  1.  $Vrfy_{pk}(m, \sigma) = 1$
  2.  $m \notin Q$ .

In this case the output of the experiment is defined to be 1.

Definition: A signature scheme  $\Pi = (Gen, Sign, Vrfy)$  is existentially unforgeable under an adaptive chosen-message attack, if for all ppt adversaries  $A$ , there is a negligible function  $neg$  such that:

$$\Pr[SigForge_{A,\Pi}(n) = 1] \leq neg(n).$$

# Overview of DL-based Signatures

- Discrete-Log-based signatures can be implemented using Elliptic Curves.
  - They are therefore more efficient than RSA-based signatures (signatures are far smaller).

$$\mathbb{Z}_p^*$$

$$\mathbb{Z}_N^0$$

$$N = p - q$$

- DL-based are preferred in Bitcoin
- Bitcoin currently uses ECDSA = Elliptic Curve Digital Signature Algorithm
- We will be learning about Schnorr signatures,
- Similar to ECDSA but have some better properties.
- ~~Many proponents of switching Bitcoin signatures to Schnorr signatures.~~

Implemented in Bitcoin in November 2021 within the Taproot upgrade as an alternative to the Elliptic Curve Digital Signature Algorithm (ECDSA)

cyclic groups  $G, g, g$

# Outline

Prover  
SK  $(x) \leftarrow \mathbb{Z}_q$

Verifier  
 $y = g^x$   
pk.

Prove knowledge of  
some  $x'$  s.t.  $g^{x'} = y$ .

- We will first construct an **Identification Scheme**

- A way to prove knowledge of a secret key corresponding to a public key without revealing the secret key

- Provides a form of "zero knowledge" (Honest Verifier Zero Knowledge)

- E.g. public key =  $g^x$ , secret key =  $x$ .

- Prove that I know  $x$ , without revealing what  $x$  is

- If I reveal  $x$ , someone can impersonate me next time.

- Use the **Fiat-Shamir transform** to convert an **Identification Scheme** into a **Signature Scheme**.

Statement: I know the discrete log of  $y$

Witness:  $x'$  s.t.  $g^{x'} = y$ .

# Identification Schemes

FIGURE 12.1: A 3-round identification scheme.

# Identification Schemes

The identification experiment  $\text{Ident}_{\mathcal{A}, \Pi}(n)$ :

1.  $\text{Gen}(1^n)$  is run to obtain keys  $(pk, sk)$ .
2. Adversary  $\mathcal{A}$  is given  $pk$  and access to an oracle  $\text{Trans}_{sk}(\cdot)$  that it can query as often as it likes.
3. At any point during the experiment,  $\mathcal{A}$  outputs a message  $I$ . A uniform challenge  $r \in \Omega_{pk}$  is chosen and given to  $\mathcal{A}$ , who responds with  $s$ . (We allow  $\mathcal{A}$  to continue querying  $\text{Trans}_{sk}(\cdot)$  even after receiving  $c$ .)
4. The experiment evaluates to 1 if and only if  $\mathcal{V}(pk, r, s) \stackrel{?}{=} I$ .

**DEFINITION 12.8** Identification scheme  $\Pi = (\text{Gen}, \mathcal{P}_1, \mathcal{P}_2, \mathcal{V})$  is secure against a passive attack, or just secure, if for all probabilistic polynomial-time adversaries  $\mathcal{A}$ , there is a negligible function  $\text{negl}$  such that:

$$\Pr[\text{Ident}_{\mathcal{A}, \Pi}(n) = 1] \leq \text{negl}(n).$$

# The Schnorr Identification Scheme

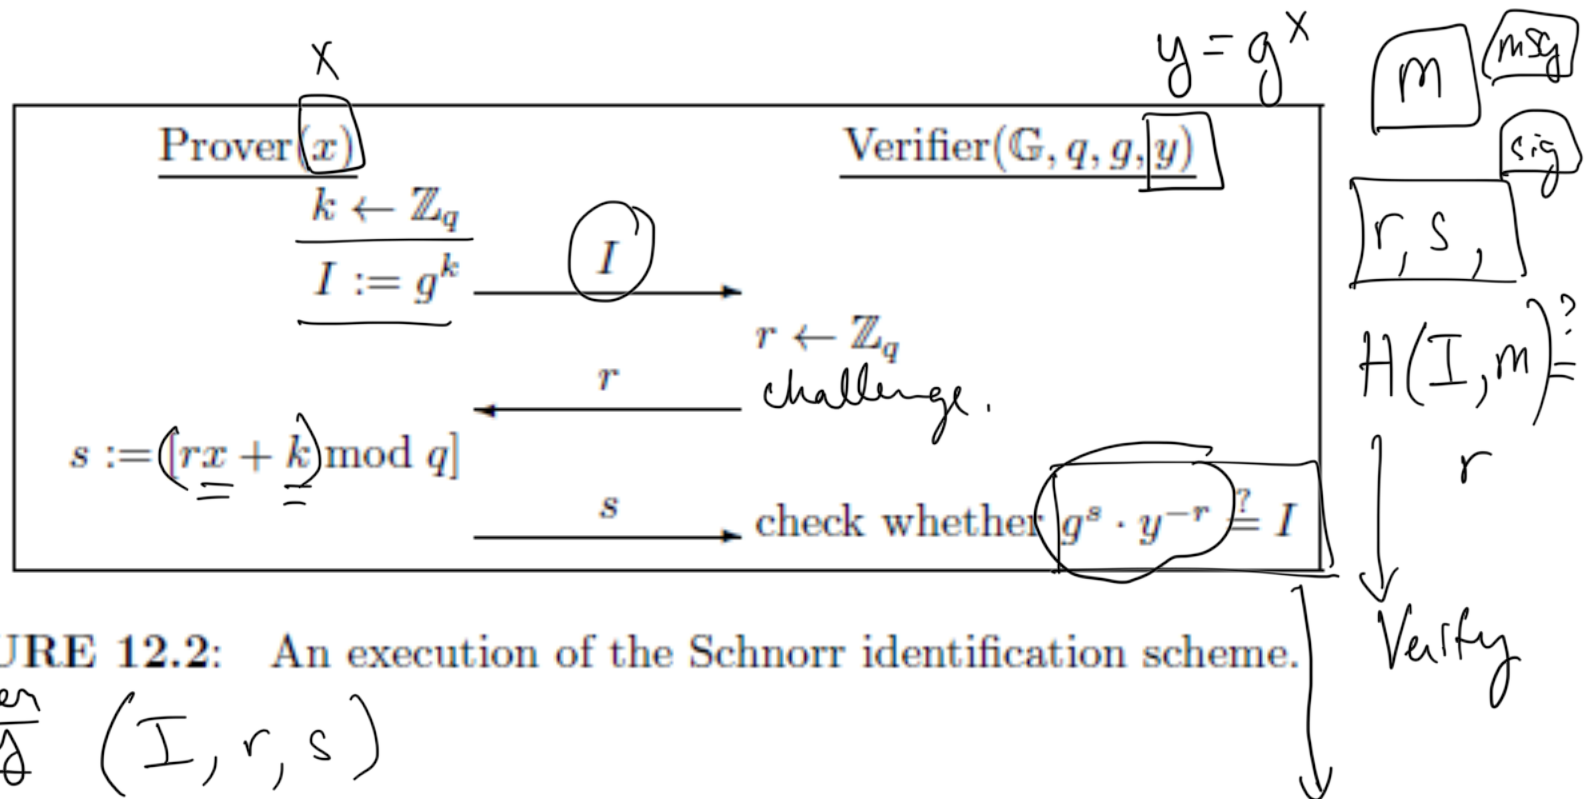

FIGURE 12.2: An execution of the Schnorr identification scheme.

Simulate <sup>given</sup>  $y$  ( $I, r, s$ )

Choose random  $r, s \leftarrow \mathbb{Z}_q$

set  $I = g^s \cdot y^{-r}$

output  $(I, r, s)$ .

$$g^{\boxed{rx+k}} \cdot \boxed{g^x}^{-r} = g^{rx - xr} \cdot g^k = g^k = I$$

# Security Analysis

Theorem: If the Dlog problem is hard relative to  $G$  then the Schnorr identification scheme is secure.

Honest Verifier

# Security Analysis

Zero Knowledge

Idea of proof:

- Oracle can generate correctly distributed transcripts without knowing  $x$ .

– How?

View of adversary  $(I, r, s)$  ( $y$ ).

fix  $r, s$  first at random

$$\text{set } I = g^s \cdot y^{-r}$$

output  $(I, r, s)$

# Security Analysis

Proof of Knowledge : Prove that a successful prover actually knows  $x$ .

Idea of proof:

- Given an attacker  $A$  who successfully responds to challenges with non-negligible probability, can construct an attacker  $A'$  who extracts the discrete log  $x$  of  $y$  by **\*\*rewinding\*\***.

"Rewinding"

Prove

Verify

SAME

$$I = g^{s_1} \cdot y^{-r_1}$$

$$I = g^{s_2} \cdot y^{-r_2}$$

$$g^{s_1} \cdot y^{-r_1} = g^{s_2} \cdot y^{-r_2}$$

$$\left( g^{s_1 - s_2} \right)^{(r_1 - r_2)^{-1}} = y^{r_1 - r_2}$$
$$= g^{\frac{s_1 - s_2}{r_1 - r_2}} = y$$

$$\text{Dlog}_g(y) = \frac{s_1 - s_2}{r_1 - r_2} = s_1 - s_2 \cdot (r_1 - r_2)^{-1} \pmod{q}$$

# From Identification Schemes to Signatures: The Fiat-Shamir Transform

## *CONSTRUCTION 12.9*

Let  $(\text{Gen}, \mathcal{P}_1, \mathcal{P}_2, \mathcal{V})$  be an identification scheme, and construct a signature scheme as follows:

- **Gen**: on input  $1^n$ , simply run  $\text{Gen}(1^n)$  to obtain keys  $pk, sk$ .  
The public key  $pk$  specifies a set of challenges  $\Omega_{pk}$ . As part of key generation, a function  $H : \{0, 1\}^* \rightarrow \Omega_{pk}$  is specified, but we leave this implicit.
- **Sign**: on input a private key  $sk$  and a message  $m \in \{0, 1\}^*$ , do:
  1. Compute  $(I, \text{st}) \leftarrow \mathcal{P}_1(sk)$ .
  2. Compute  $r := H(I, m)$ .
  3. Compute  $s := \mathcal{P}_2(sk, \text{st}, c)$Output the signature  $(r, s)$ .
- **Vrfy**: on input a public key  $pk$ , a message  $m$ , and a signature  $(r, s)$ , compute  $I := \mathcal{V}(pk, r, s)$  and output 1 if and only if  $H(I, m) \stackrel{?}{=} r$ .

The Fiat-Shamir transform.

# Security Analysis

Theorem: Let  $\Pi$  be an identification scheme, and let  $\Pi'$  be the signature scheme that results by applying the Fiat-Shamir transform to it. If  $\Pi$  is secure and  $H$  is modeled as a random oracle, then  $\Pi'$  is secure.

# The Schnorr Signature Scheme

## CONSTRUCTION 12.12

Let  $\mathcal{G}$  be as described in the text.

- **Gen:** run  $\mathcal{G}(1^n)$  to obtain  $(\mathbb{G}, q, g)$ . Choose uniform  $x \in \mathbb{Z}_q$  and set  $y = g^x$ . The private key is  $x$  and the public key is  $(\mathbb{G}, q, g, y)$ . As part of key generation, a function  $H : \{0, 1\}^* \rightarrow \mathbb{Z}_q$  is specified, but we leave this implicit.
- **Sign:** on input a private key  $x$  and a message  $m \in \{0, 1\}^*$ , choose uniform  $k \in \mathbb{Z}_q$  and set  $I := g^k$ . Then compute  $r := H(I, m)$ , followed by  $s := [rx + k \text{ mod } q]$ . Output the signature  $(r, s)$ .
- **Vrfy:** on input a public key  $(\mathbb{G}, q, g, y)$ , a message  $m$ , and a signature  $(r, s)$ , compute  $I = g^s \cdot y^{-r}$  and output 1 if  $H(I, m) \stackrel{?}{=} r$ .

The Schnorr signature scheme.
