Overview of Presentation

- ***Description of Experiment***
 - Facility
 - 12-sensor hot-wire probe for velocity and vorticity measurements
 - Optical arrangement for Mie-scattering scalar concentration measurements
- ***Description of LES***
 - Computational Scheme
 - Initial Conditions
 - Grid Refinement
- ***Results***
 - Statistics
 - Flow Structure
 - Transport Mechanisms
- ***Summary***

Photo of two-stream mixing layer in transition

Turbulent “roller” vortices are seen downstream. $R_\theta \sim 1600$ at measurement location in self-similar region.

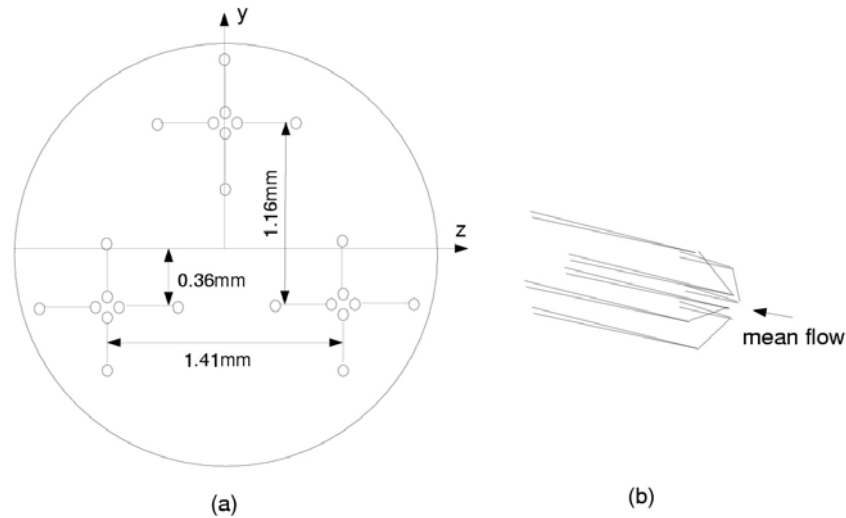

Experimental Setup

Twelve-sensor probe for velocity vector & velocity gradient measurements

Large-eddy simulation

- Fractional step method with central 2nd order finite differences
- Staggered grid with $380 \times 96 \times 96$ points (3.5M)
- Boundary conditions:
 - Inflow: parallel B.L. computations
 - Outflow: convective b.c.
 - Freestream: radiative b.c.
- Scalar transport: simulated tracking massless particles (10M)

Matching Experimental & LES Inflow Conditions

Comparison Properties

	Re_θ	$d\theta/dx$
Present Experimental Study	1,590	0.013
Present Numerical Study (LES)	1,500-3,900	0.013
Loucks [35]	2,483	0.016
	1,792	
	432	
Bell & Metha [7]	2,800	0.010
	1,900	
	1,570	
Rogers & Moser (DNS) [50]	1,500-2,000	0.014

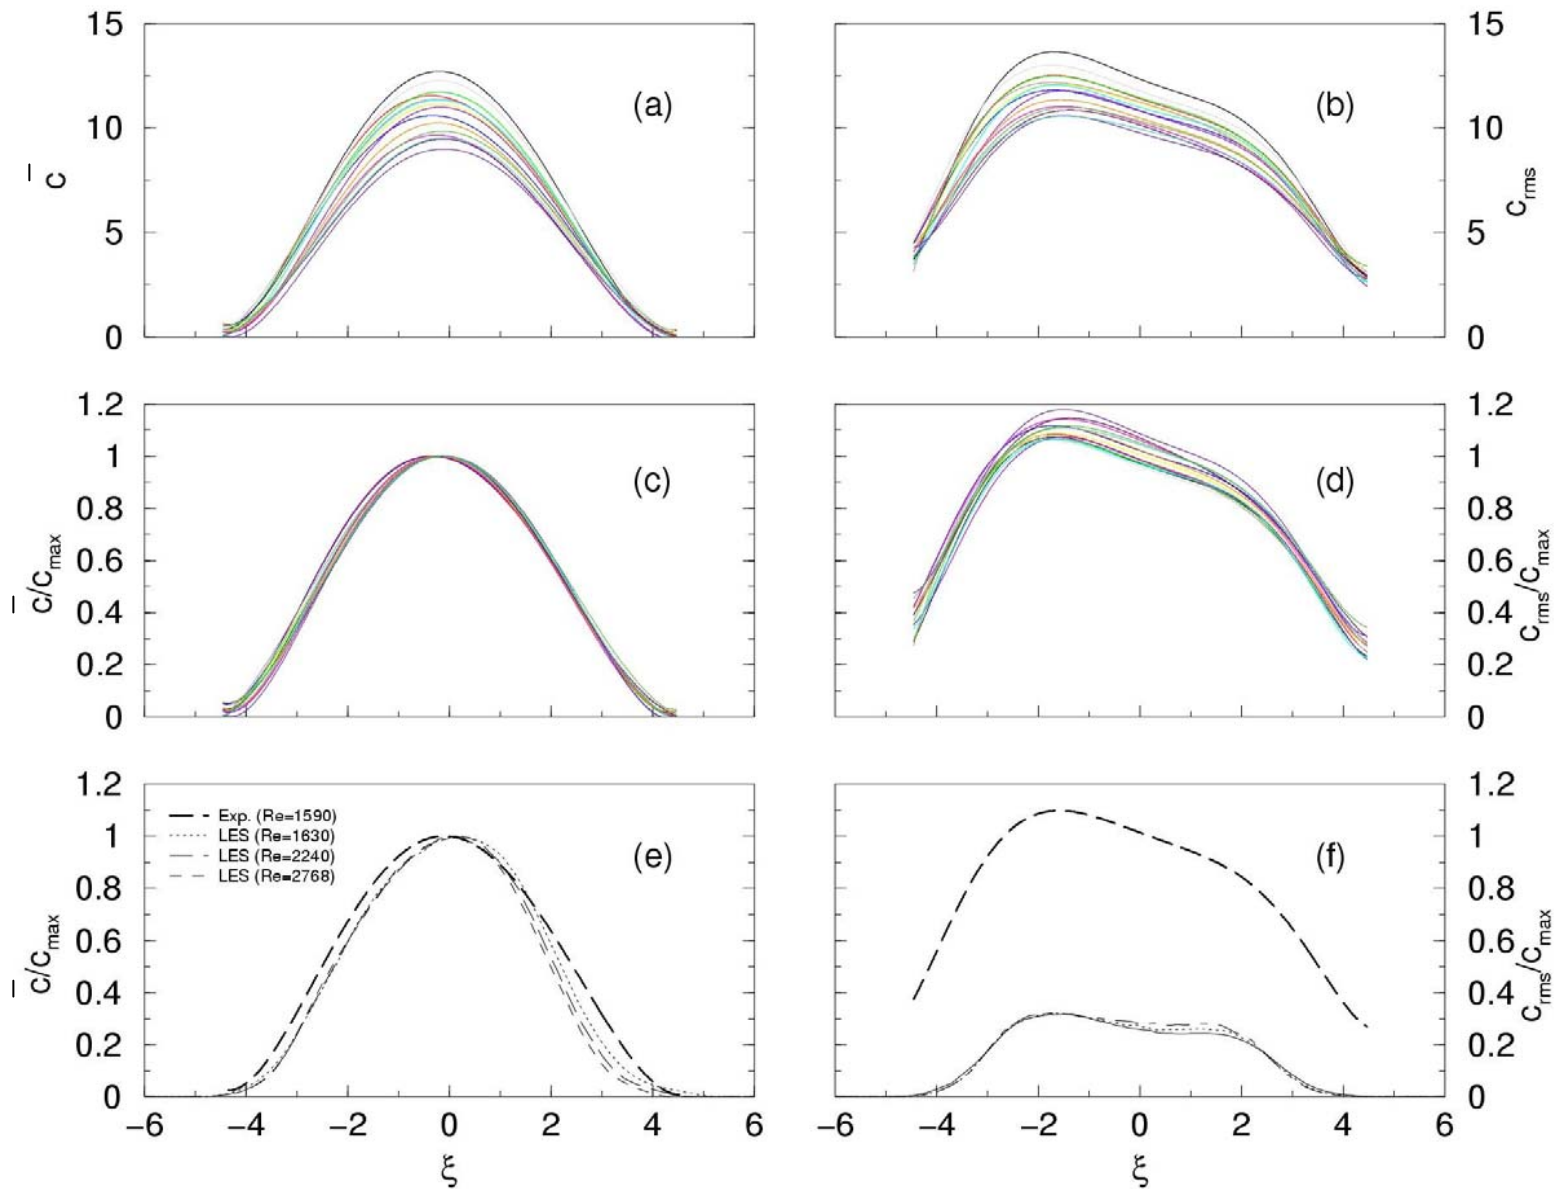

Velocity Statistics

Concentration Statistics

Scalar & Momentum Fluxes

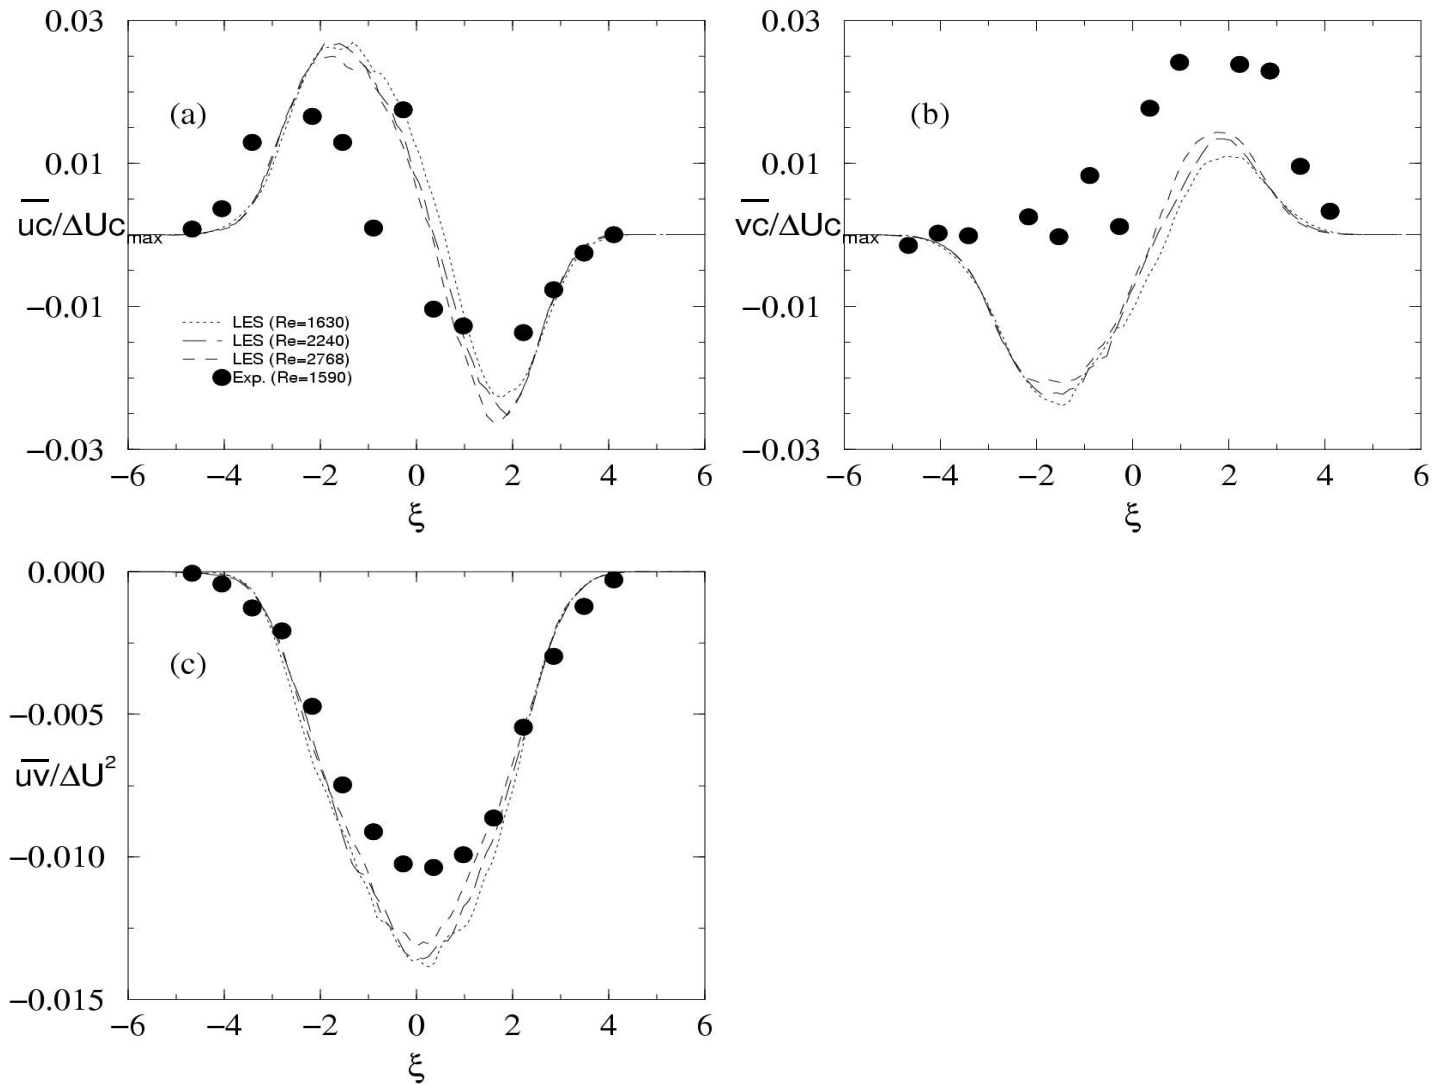

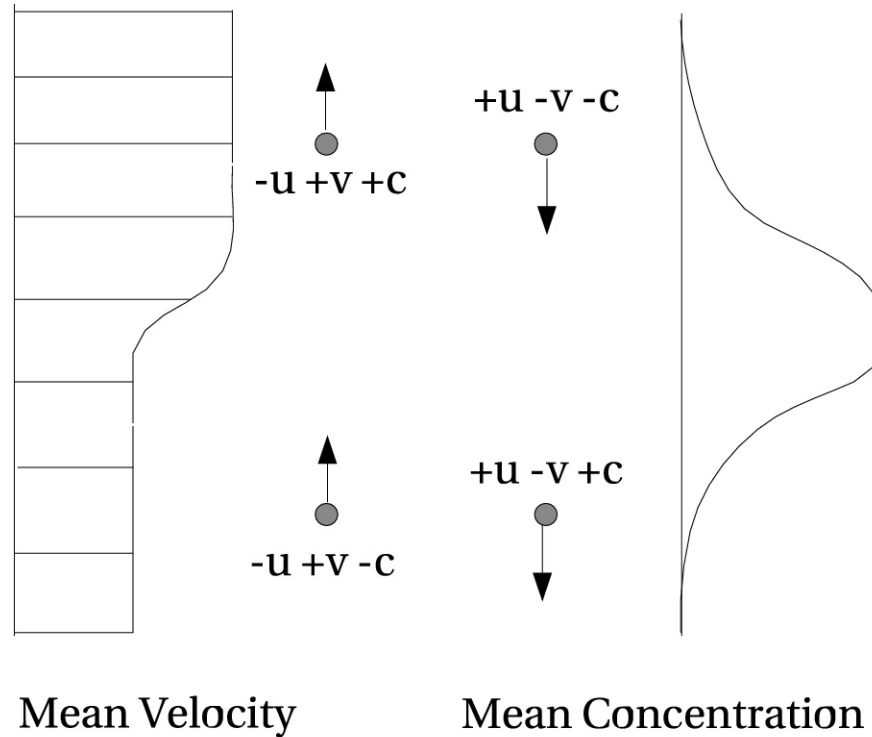

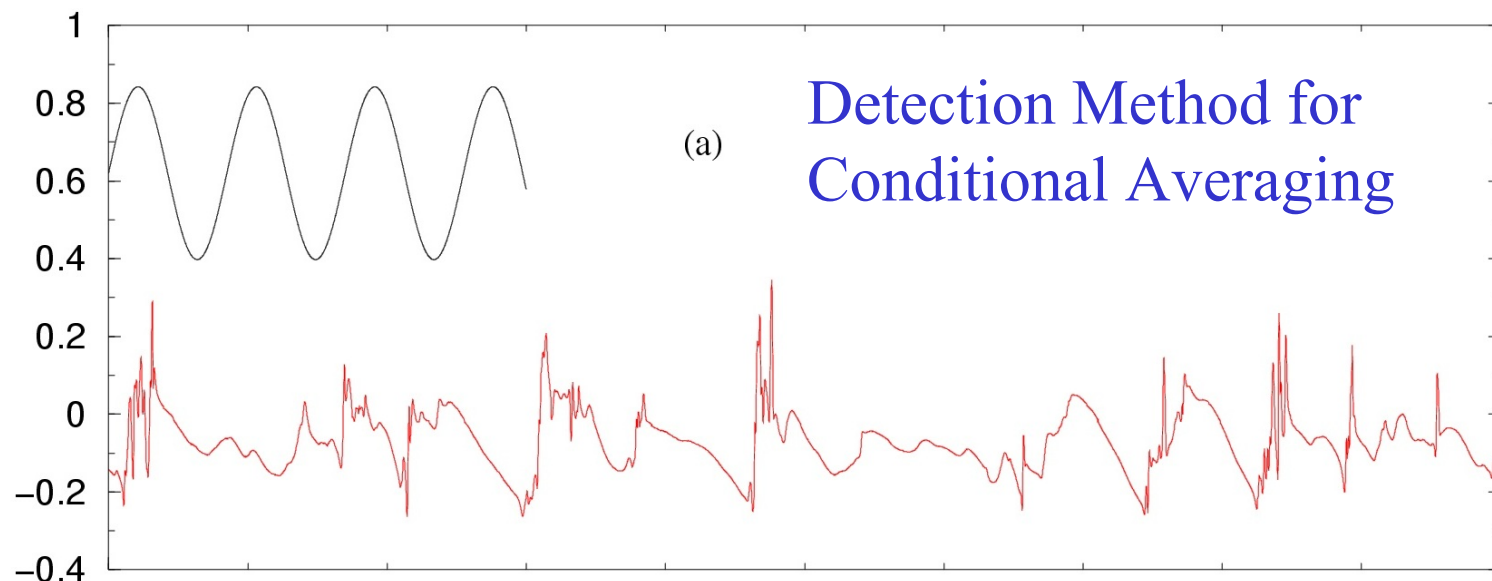

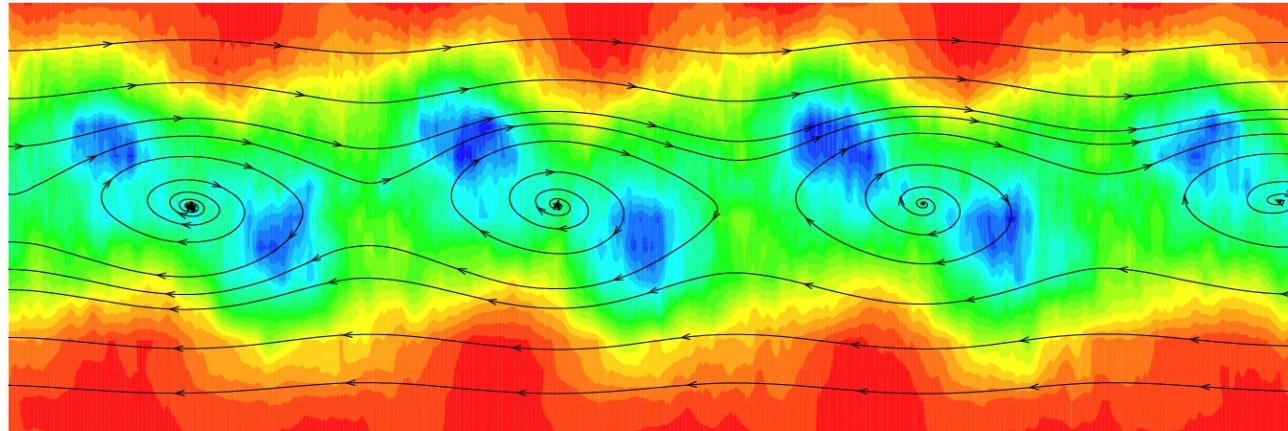

Illustration of Mean Gradient Transport

Conditionally Averaged “Roller” Vortices (streamlines) & Reynolds Shear Stress (color contours)

Conditionally Averaged scalar fluxes

$\langle uc \rangle$

$\langle vc \rangle$

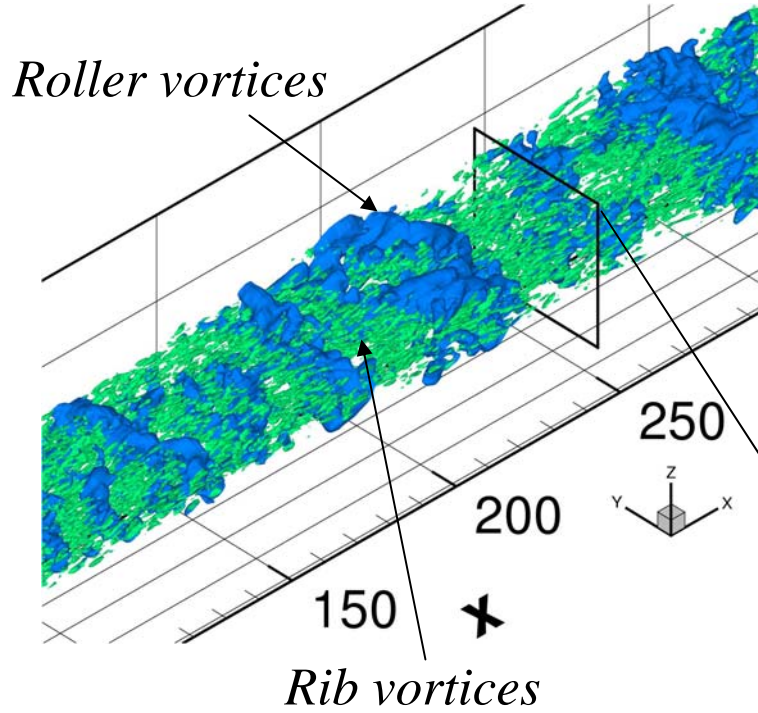

Spanwise Averaged “Roller” Vortices & Scalar Fluxes from LES

$\langle uc \rangle$

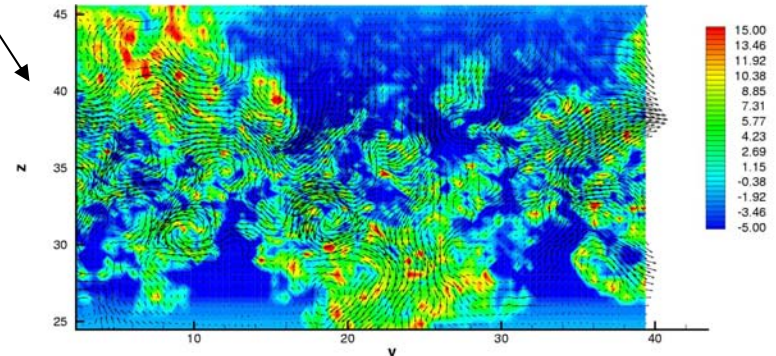

$\langle vc \rangle$

Scalar fluctuations, c

Scalar flux, vc

Summary

- A Multi-sensor hot-wire probe and optical system was used to measure the scalar and momentum flux in a two-stream mixing layer.
- LES was used to study the scalar and momentum transport processes in this flow
- Experimental and Computational velocity and vorticity field statistics are in reasonable agreement with each other and sources from the literature.
- Conditional averaging revealed the spatial locations of the highest scalar and momentum flux intensities occur in the “braid” on the periphery of the “roller” vortices.
- An instantaneous realization of the 3-D LES field revealed that the scalar transport is primarily of the mean gradient type and is closely associated with the pumping action between the “rib” vortices in the “braid” between the rollers.
